lecture 14 Gamma-ray astronomy

astrophysical production of gamma rays has been discussed in lecture 12, Gaisser chapter 11

High-energy gamma rays

In addition to charged particles we obtain information on the high-energy universe from gamma rays. $E \sim 100 \text{ MeV} \longrightarrow 50 \text{ TeV}$

Production & interaction

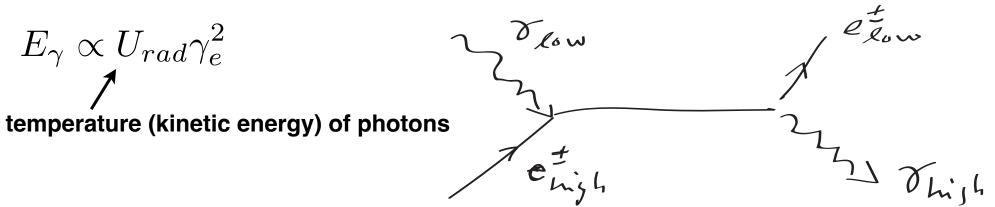

1) synchrotron radiation of electrons in B fields Depending on the energy of the electron and the strength of the B field, the energy of photons ranges from radio (meV) to ~10 MeV

$$E_{\gamma} \propto B^2 \gamma^2$$

radiation is polarized

2) Inverse Compton scattering energy of electrons is transferred to photons "heating of photons through electrons"

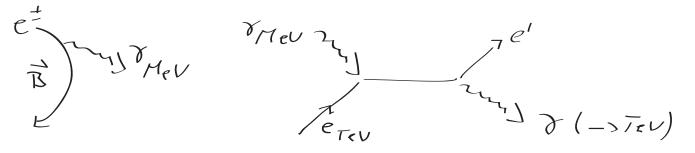

3) Hadronic interactions

$$p + ISM \to \pi^0 + X$$
$$\gamma + \gamma$$

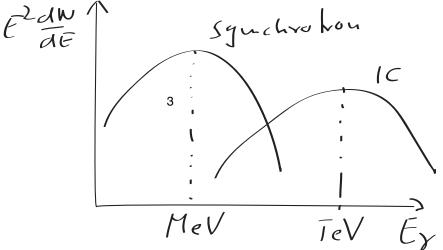

requires the presence of hadronic particles

- 4) Bremsstrahlung e+target --> Bremsstrahlung $E_{\gamma} \approx \frac{E_e}{2}$ (power law)
- 5) important combination of 1) and 2) synchrotron self compton (SSC)

the photons for inverse Compton scattering are produced in-situ

typical form of spectrum

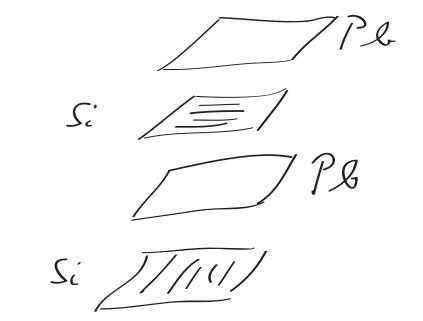

Measurement of photons 1) detection in space

> Fermi satellite electromagnetic calorimeter 10 layers of Pb converter $\gamma \rightarrow e^+e^$ interspaced with 12 layers of Si strip detectors

electromagnetic cascade --> trajectory

$$\Longrightarrow \sum E \to E_{\gamma}$$

up to $E_{\gamma} \approx 10 - 20 \text{ GeV}$

GAMMA-RAY LARGE AREA SPACE TELESCOPE

GLAST/Fermi

10 Layers of 0.5 rad Length Converter (pb)

- 12 Layers of XY Silicon Strips
- 🚧 Gamma Rays
- Positrons/Electrons

2) atmospheric Cherenkov telescopes

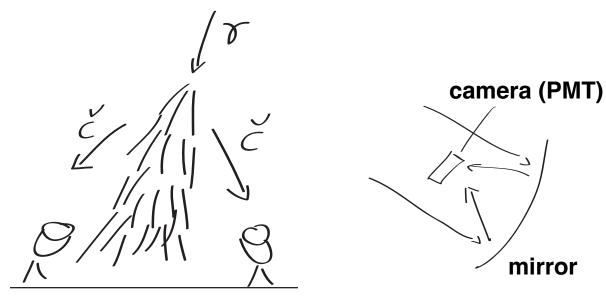

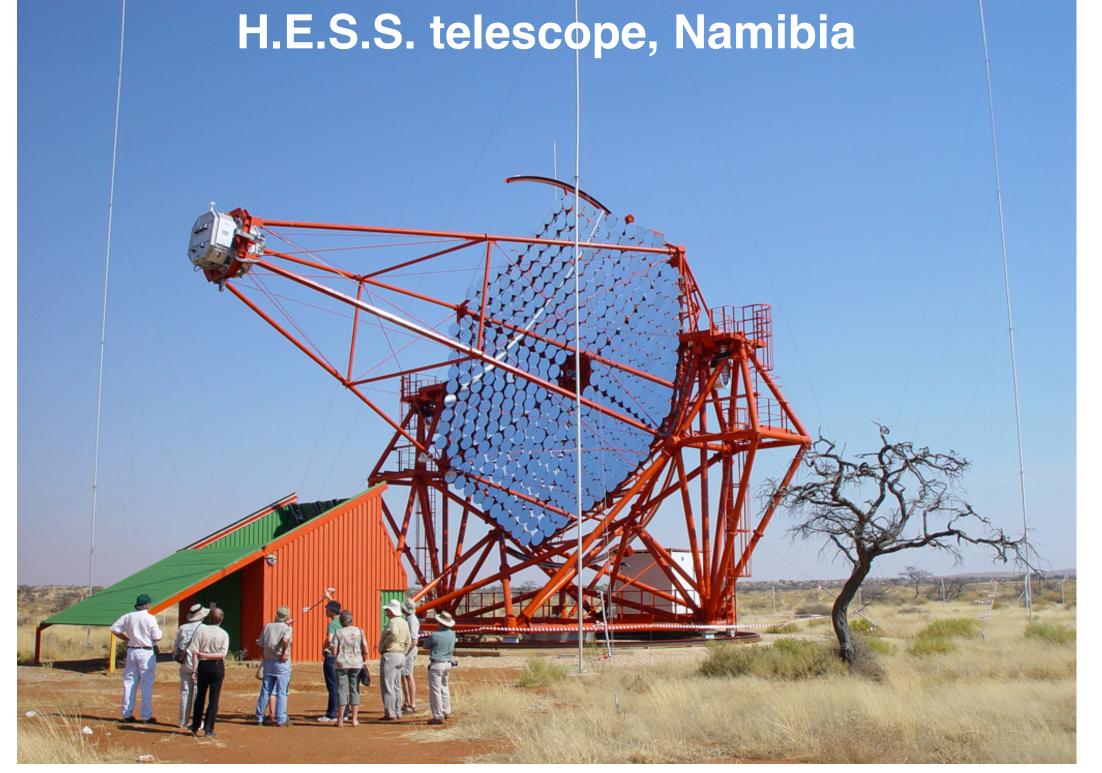

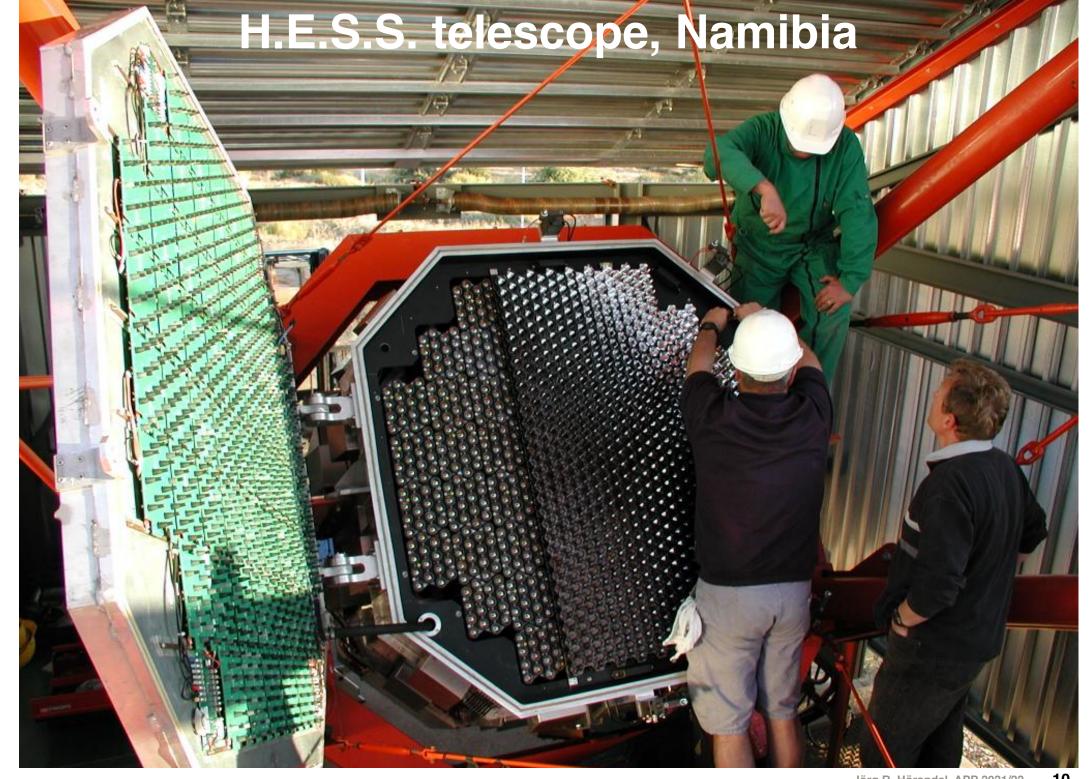

image of shower is recorded with a fast camera (PMT)

total number of photons --> E_{θ} field of view ~4°

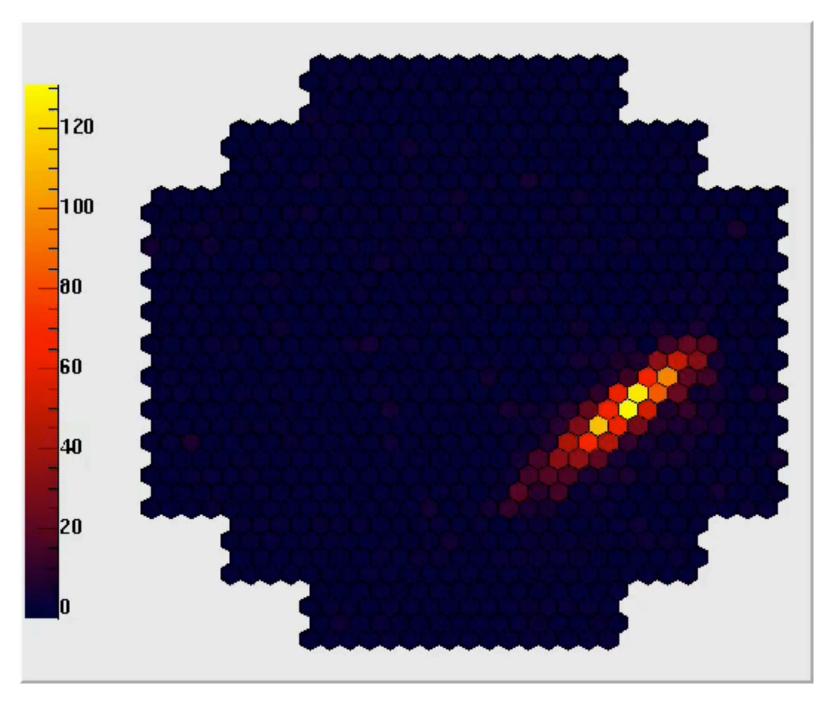

stereo observations
--> 3 dim trajectory of shower in atmosphere
--> direction of the incoming photon

IACT = Imaging Atmospheric Cherenkov¹⁰**Telescope**

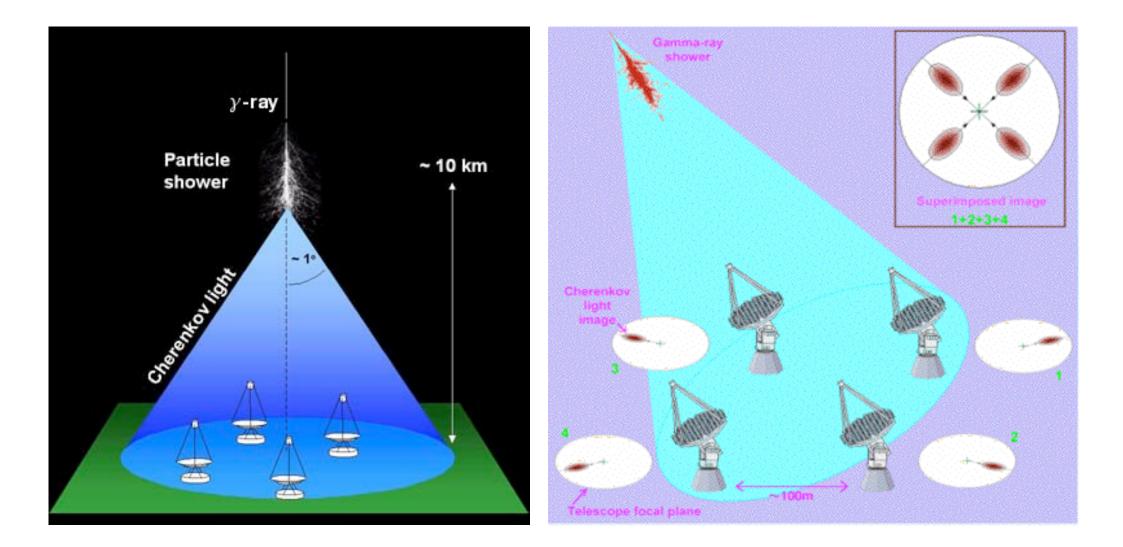

H.E.S.S. telescope, Namibia

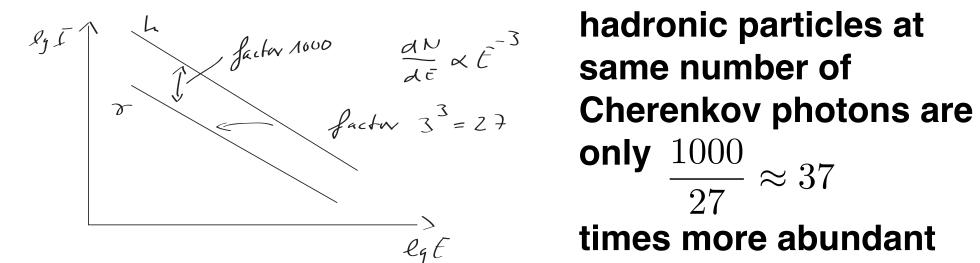

stereo observation

high background of hadronic particles reduction through two effects:

1) hadronic particles produce only 1/3 Cherenkov light as photons of the same energy

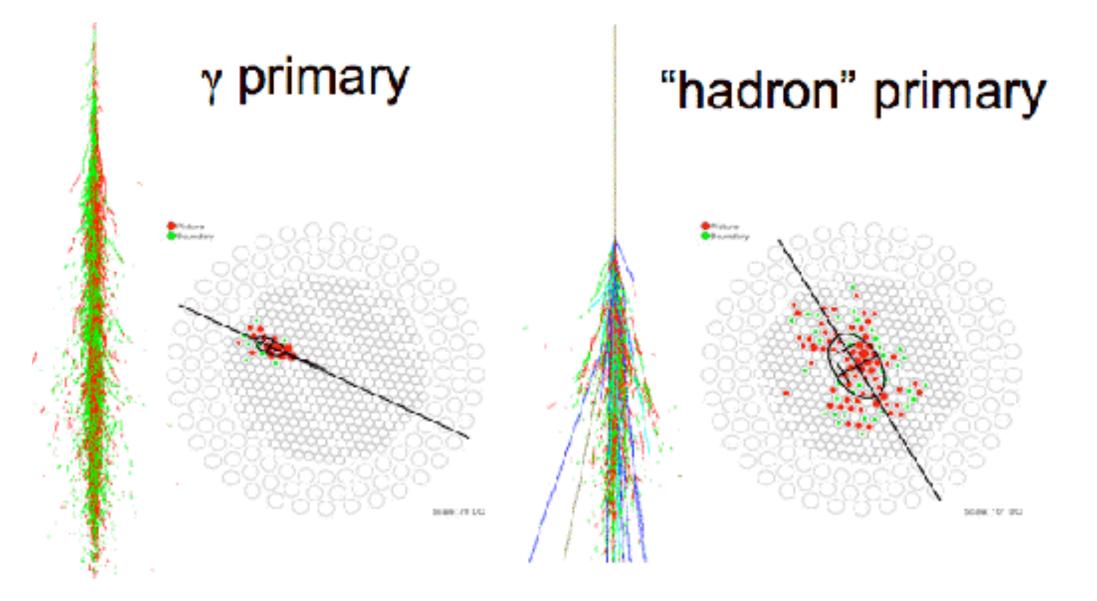

hadronic particles at only $\frac{1000}{27} \approx 37$ times more abundant

2) pattern recognition in Cherenkov image

e/m cascades produce "smoother" images hadronic interaction length $\lambda_I = 90 \ \frac{\mathrm{g}}{\mathrm{cm}^2}$ VS radiation length $X_0 = 36 \frac{g}{cm^2}$

gamma-hadron separation

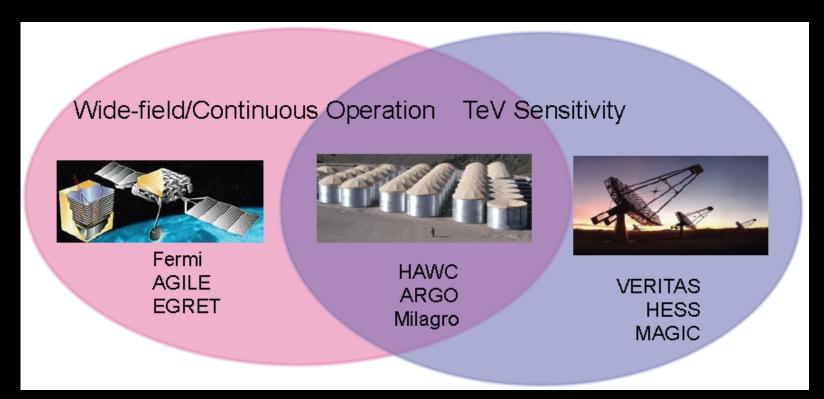

Complementarity of gamma-ray instruments

- Space-based detectors - continuous full-sky coverage in GeV

- Ground-based detectors have TeV sensitivity

Current Imaging Atmospheric Cherenkov Telescopes (IACTs) have excellent energy and angle resolution, but FoV of 0.003 sr and duty cycle of 10%
 Particle detectors have an aperture > 2 sr and duty cycle of 90% but angular resolution of ~0.6° (@ 1 TeV)

M. Lemoine-Goumard, 34th ICRC, The Hague, 6th August 2015

INSTRUMENTS

M. Lemoine-Goumard, 34th ICRC, The Hague, 6th August 2015

Status of VERITAS

VERITAS has been operating smoothly since 2007 with 4 12m IACTs.

Two major upgrades since inauguration: In 2009, relocation of one of the telescopes In 2011-2012, replaced the L2 trigger system and new high efficiency PMTs Since fall 2012, observations carried out under bright moonlight: detection of flaring activity from the BL Lac object 1ES 1727+502

Energy range: 85 GeV to > 30 TeV Sensitive to 1% Crab in ~25 hours Angular resolution ~0.1° (68% containment)

VERITAS Highlight, 90, 676, 762

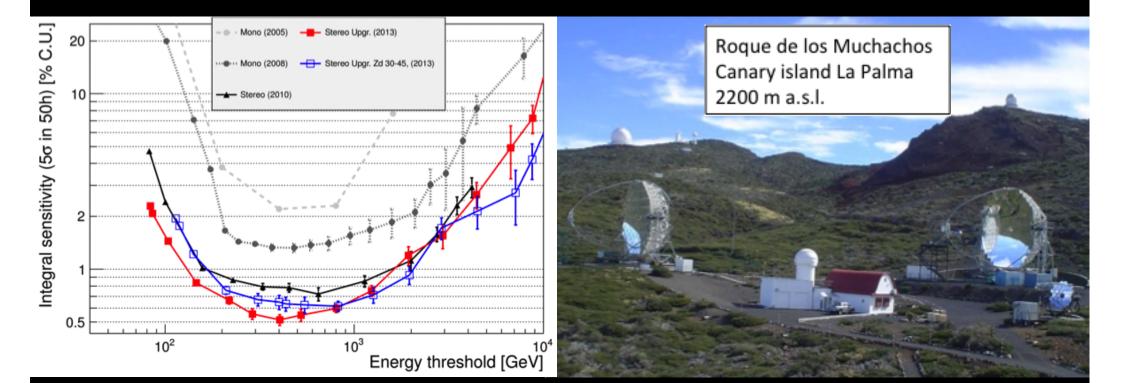

M. Lemoine-Goumard, 34th ICRC, The Hague, 6th August 2015

Status of MAGIC II

MAGIC is a system of two 17m diameter IACTs located at 2200m at La Palma 2 major upgrades in 2011-2012 (Camera, Data Acquisition)

During Winter 2013-2014, a new system (sum-trigger) was implemented for stereoscopic observations after several years of development E_{threshold} (trigger): ~ 50 GeV E_{threshold} Sum-Trigger: ~35 GeV Energy resolution: (15-20) % Angular resolution: (0.05-0.1)° Sensitivity: ~ 0.6% Crab/50h MAGIC Highlight, 60, 68, 101, 579

Status of H.E.S.S. II

HESS is an array of four 12m IACTs + one 28m telescope (CT5, FoV ~ 3.5°)

CT5 is operationnal since 2012 Energy range from 30 GeV to 100 TeV Focus system of CT5 under study => Focusing close to the altitude of shower maximum maximizes the γ -ray acceptance close to the energy threshold

Major upgrade of HESS I camera from 2015-2016: reducing the dead time of the cameras, improving the overall performance of the array and reducing the system failure rate related to aging

62, 98, 107, 108, 1011, 1046

Status of HAWC

HAWC Highlight, 96, 112, 418, 529, 692, 716, 739, 829

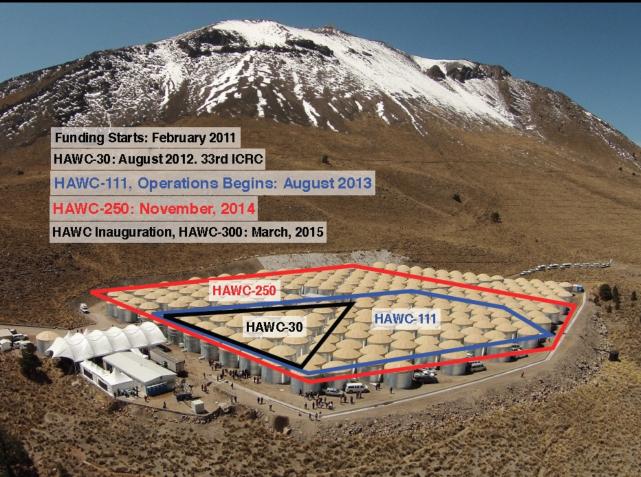

Array of water Cherenkov detectors (WCDs) spread on a 22 000 m2 area Located on the slope of the Sierra Negra Volcano in Mexico HAWC construction ended in March 2015 but data collection started already 2 years before, producing the first scientific results

HAWC Inauguration, HAWC-300: March, 2015

100 GeV - 100 TeV Sensitivity

Public data release of all-sky data in 2017

HAWC Sparse Outrigger Array: Enhanced Sensitivity above 10 TeV

M. Lemoine-Goumard, 34th ICRC, The Hague

Status of ARGO-YBJ

Tibet, China, 4300 m above sea level Full coverage with RPC detectors

849, 162

Large field of view

Zenith angle < 50° Survey of the Galactic plane at 25° < 1 < 100° and 130° < 1 < 200°

Energy threshold 300 GeV => Overlaps the Fermi-LAT energy range

Angular resolution 0.99° for Npad > 100

ARGO-YBJ

Five years of stable operation until February 2013 Sky survey of the Northern hemisphere at 24% Crab flux sensitivity

Status of Tibet ASy + MD

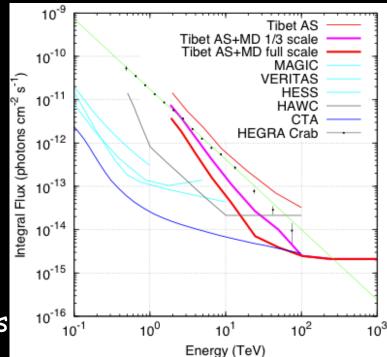

37000m2 air shower particle detector array

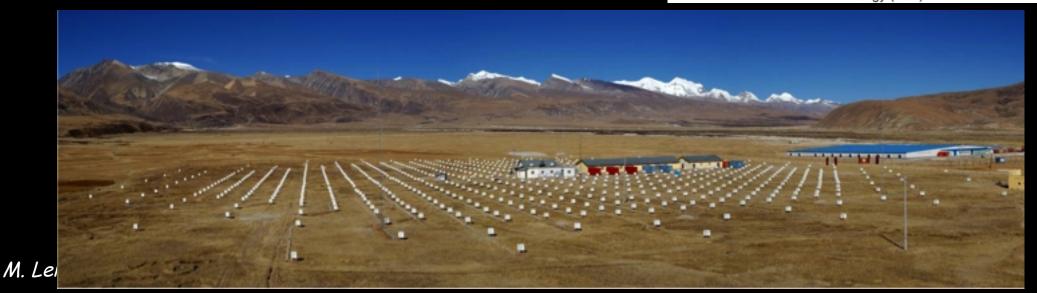

789 scintillator detectors, at 4300m a.s.l.

Tibet III in operation since 1999

Energy interval: ~TeV to 100 PeV Angular resolution: ~0.2° @ 100 TeV

Muon detector array under construction: data taking has started with 5/12 since 2014 reduce background CRs by selecting γ-like events

diffuse gamma radiation

1) radio wavelengths

synchrotron radiation from electrons in B fields intensity $\propto B\rho_e$

halo of galaxies are more extended than the visible region

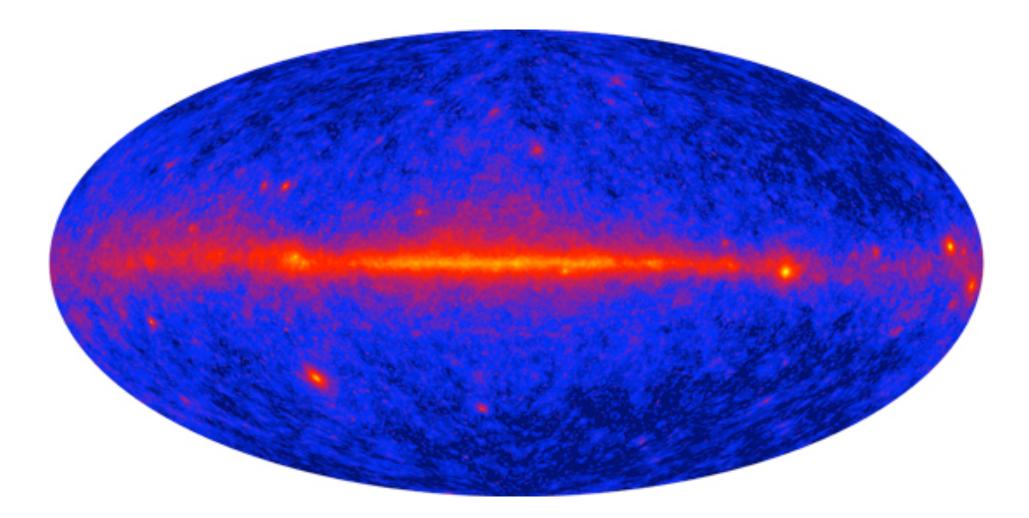

- --> confirmation that cosmic rays (electrons) propagate in the galactic halo
- 2) also diffuse gamma radiation observed E>100 MeV origin: $CR + ISM \rightarrow \pi^0 \rightarrow \gamma + \gamma$

--> direct hint that cosmic rays (hadrons) are not a local phenomenon they propagate in the halo of the Milky Way and they

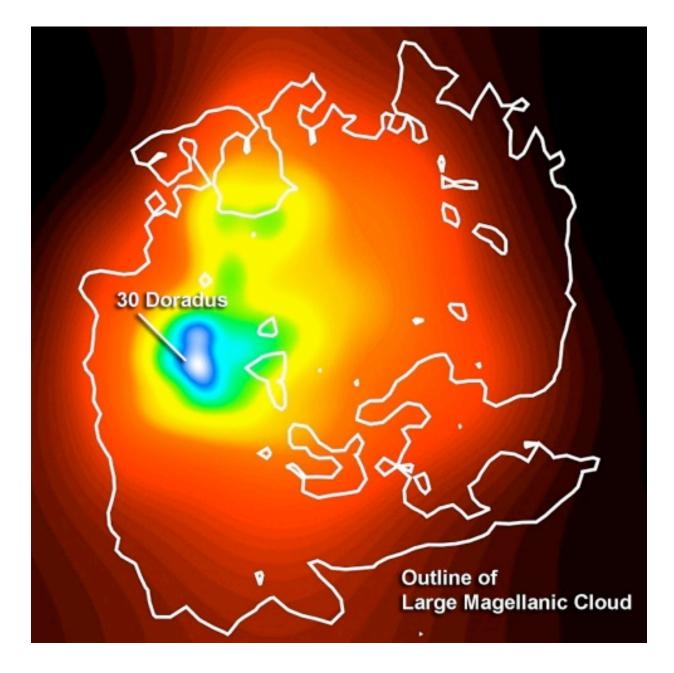

exist in other galaxies

diffuse radio background of the Milky Way

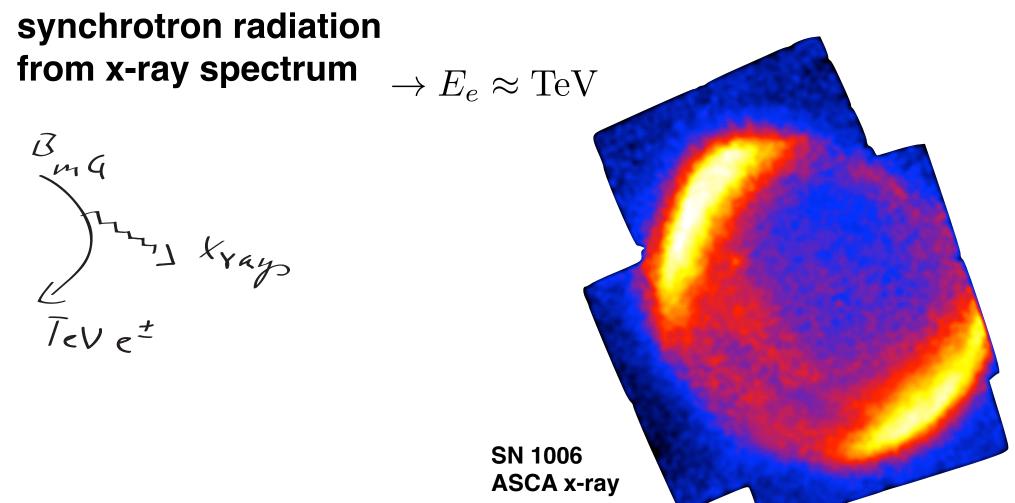

The Fermi All Sky Map, showing the diffuse galactic gamma-ray background from the Milky Way. Courtesy of NASA/DOE/International LAT Team

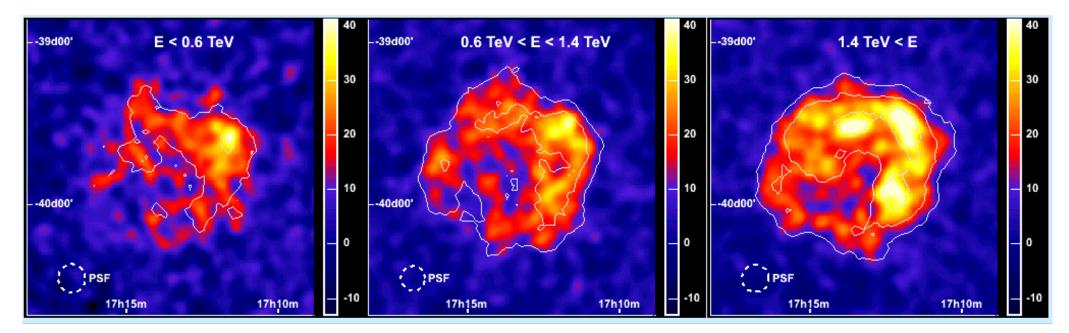

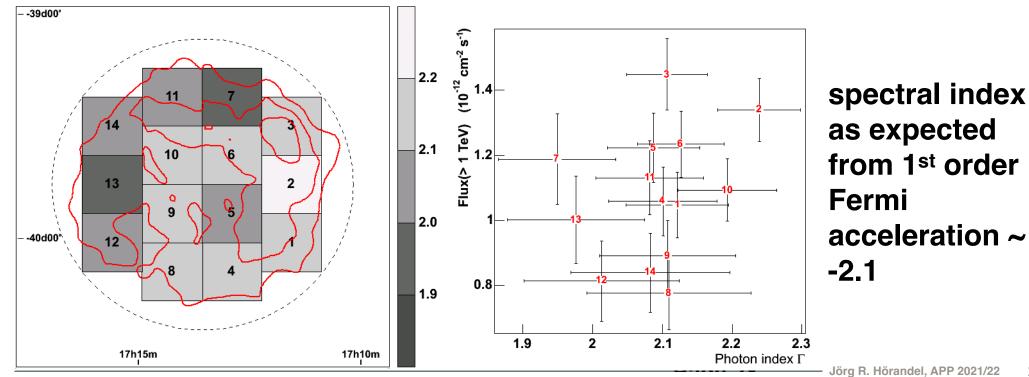

Fermi's Large Area Telescope shows that an intense star-forming region in the Large Magellanic Cloud named 30 Doradus is also a source of diffuse gamma rays. Brighter colors indicate larger numbers of detected gamma rays. point sources 1) galactic sources supernovae

1995 first hint that electrons are accelerated in B fields of SNR

H.E.S.S. supernova remnant RXJ 1713

coffee break until 14:30

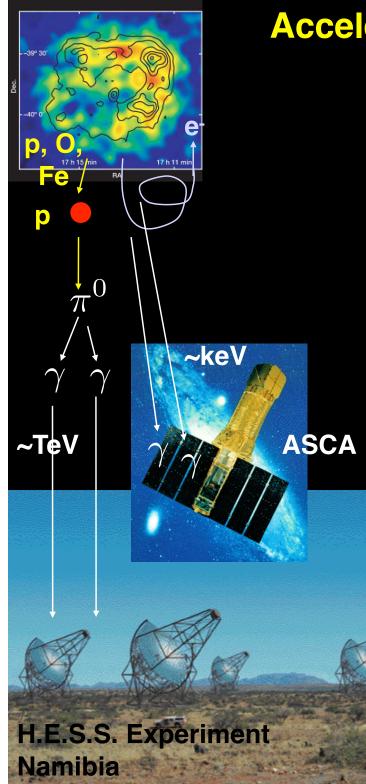

2004: H.E.S.S. telescopes observation of SNR RXJ1713

observed spectrum:

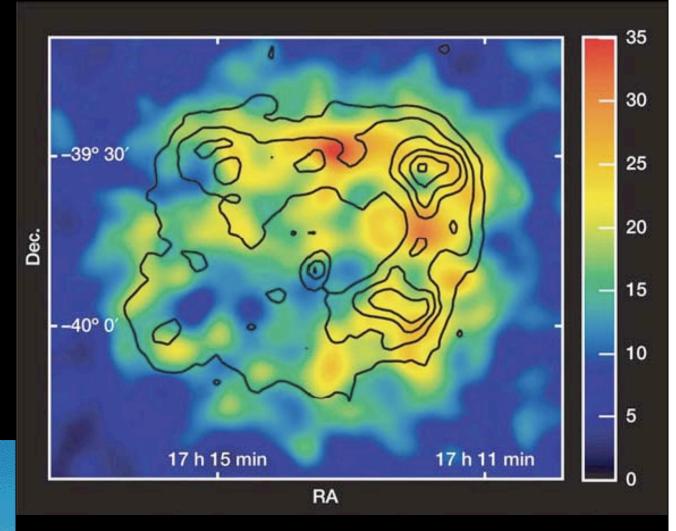

- acceleration of electrons: SSC, i.e. inverse Compton effect of γ s on TeV electrons
- acceleration of hadrons (nuclei): γ s originate from π^0 decay

which process dominates?

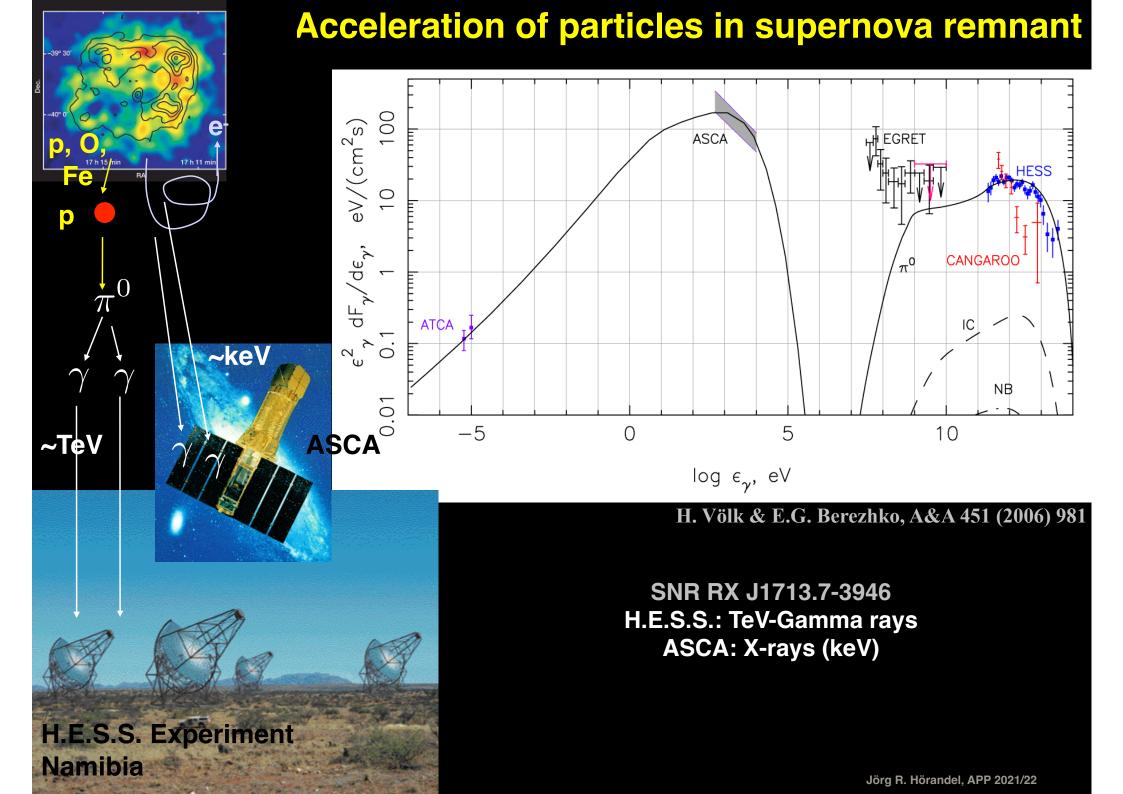

Acceleration of particles in supernova remnant

SNR RX J1713.7-3946 H.E.S.S.: TeV-Gamma rays ASCA: X-rays (keV)

F. Aharonian et al, Nature 432 (2004) 75

Acceleration of hadrons (H. Völk et al)

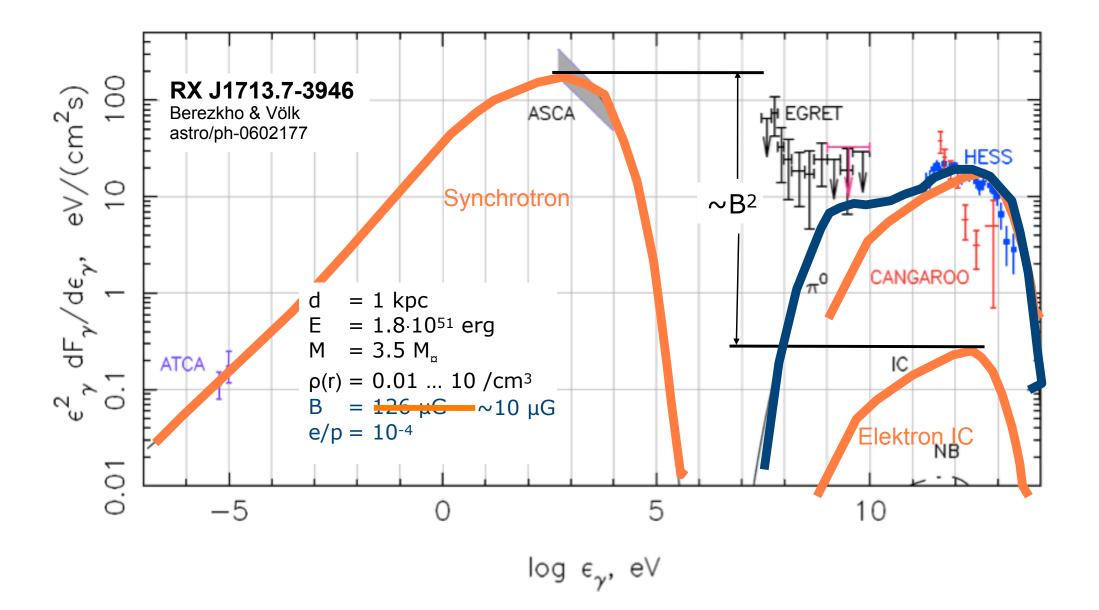

Accelerated cosmic rays modify the B field at the SNR (self amplification) --> B field in SNR is (much) larger than in ISM ~100 μ G instead of ~3 μ G

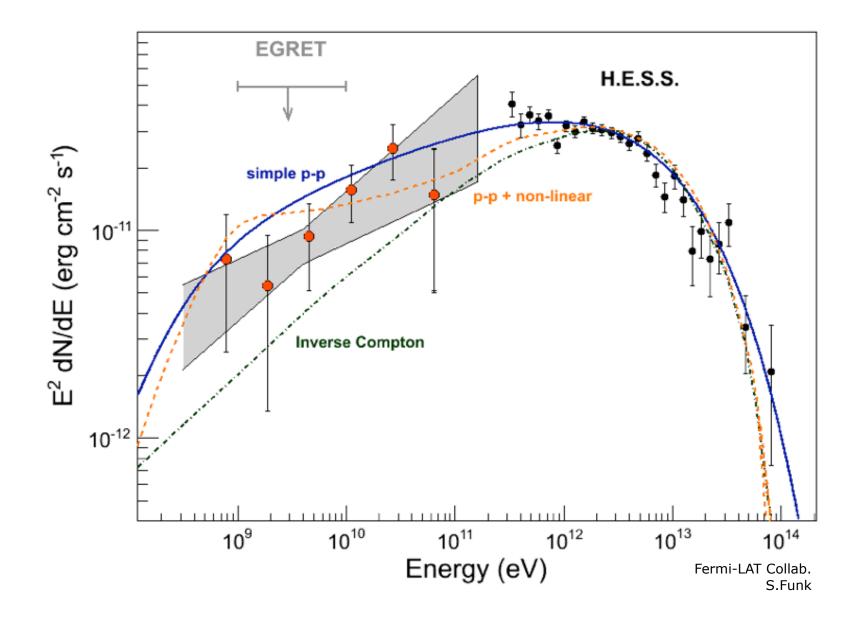

--> effective production of synchrotron radiation --> observed flux of x rays and radio can be explained by a moderate electron number density

--> fraction of inverse Compton contribution is relatively small --> most likely the observed TeV gamma rays are from π^0 decay --> hint for the acceleration of hadrons in SNR

Rg E²I (synchrohum =>Se (K HESS - ic)

BUT: is self amplification realized in nature?

HESS: Acceleration of Petaelectronvolt protons in the Galactic Centre

Nature 531, 476 (2016)

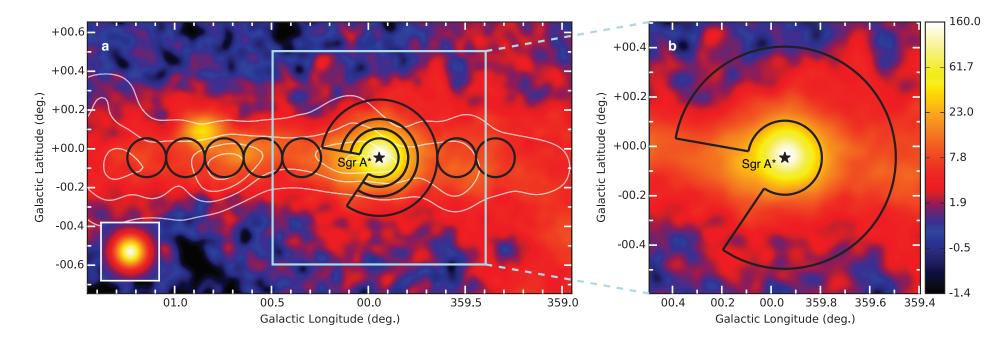

Figure 1: VHE γ -ray image of the Galactic Centre region. The colour scale indicates counts per $0.02^{\circ} \times 0.02^{\circ}$ pixel. *Left panel:* The black lines outline the regions used to calculate the CR energy density throughout the central molecular zone. A section of 66° is excluded from the annuli (see Methods). White contour lines indicate the density distribution of molecular gas, as traced by its CS line emission³⁰. The inset shows the simulation of a point-like source. *Right panel:* Zoomed view of the inner ~ 70 pc and the contour of the region used to extract the spectrum of the diffuse emission.

HESS: Acceleration of Petaelectronvolt protons in the Galactic Centre

Nature 531, 476 (2016)

Here we report deep gamma-ray observations with arcminute angular resolution of the Galactic Centre regions, which show the expected tracer of the presence of PeV particles within the central 10 parsec of the Galaxy. We argue that the supermassive black hole Sagittarius A* is linked to this PeVatron. Sagittarius A* went through active phases in the past, as demonstrated by X-ray outbursts and an outflow from the Galactic Center. Although its current rate of particle acceleration is not sufficient to provide a substantial contribution to Galactic cosmic rays, Sagittarius A* could have plau- sibly been more active over the last ~ 10^{6–7} years, and therefore should be considered as a viable alternative to supernova remnants as a source of PeV Galactic cosmic rays.

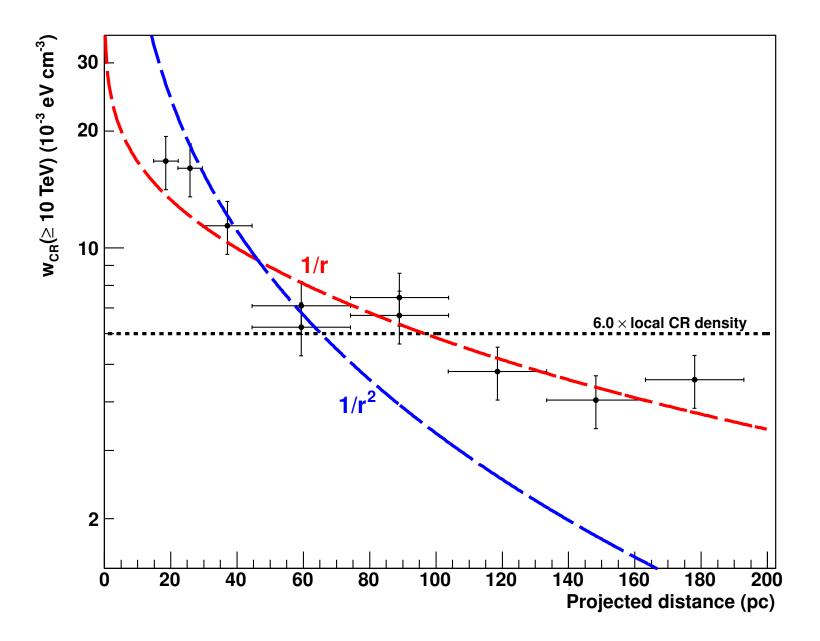

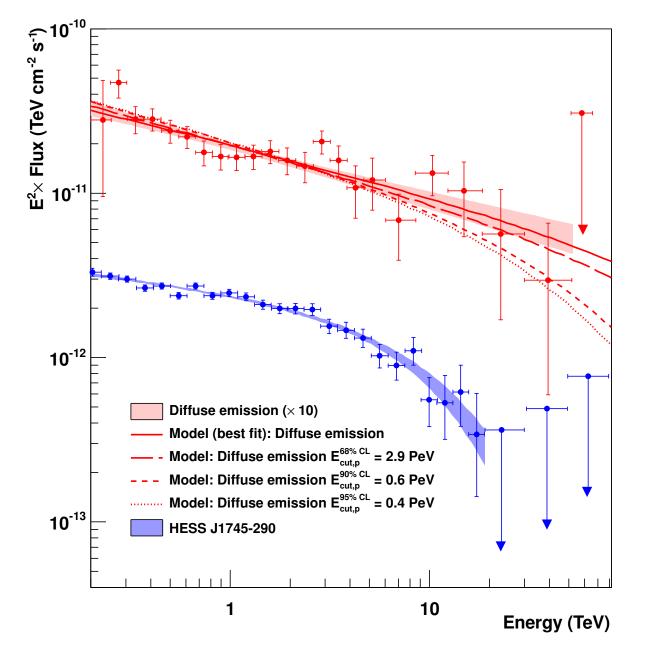

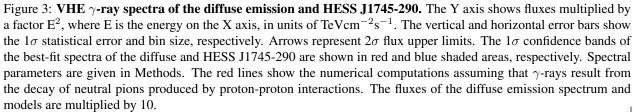

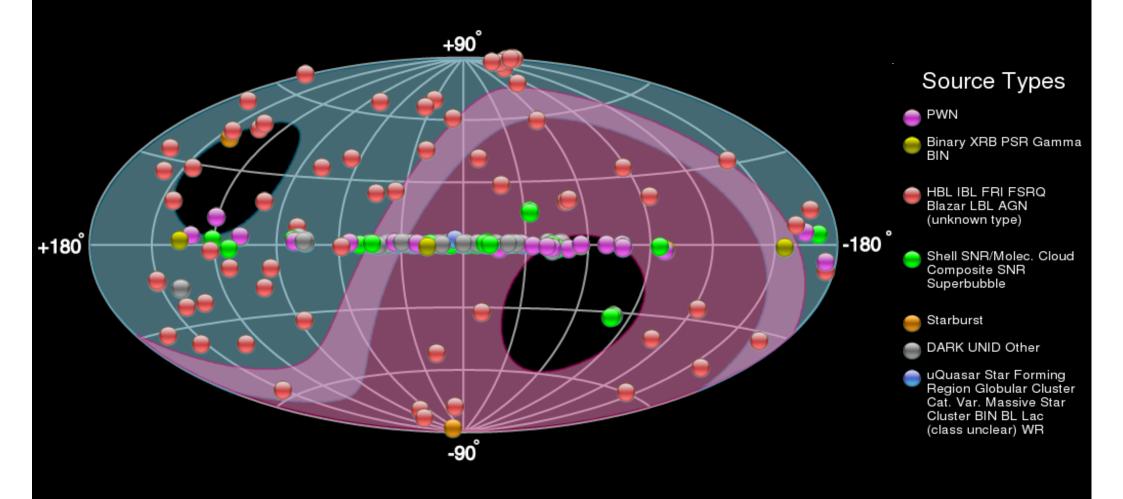

Figure 2: Spatial distribution of the CR density versus projected distance from Sgr A*. The vertical and horizontal error bars show the 1σ statistical plus systematical errors and the bin size, respectively. A fit to the data of a 1/r (red line, $\chi^2/d.o.f. = 11.8/9$), $1/r^2$ (blue line, $\chi^2/d.o.f. = 73.2/9$) and an homogeneous (black line, $\chi^2/d.o.f. = 61.2/9$) CR density radial profiles integrated along the line of sight are shown. The best fit of a $1/r^{\alpha}$ profile to the data is found for $\alpha = 1.10 \pm 0.12$ (1σ). The 1/r radial profile is clearly preferred by the H.E.S.S. data.

The TeV sky today: a large variety of sources

Already 162 detected sources reported in the TeV Catalog in August 2015 ! 65 sources are extragalactic - 70 are Galactic - 27 UNID

M. Lemoine-Goumard, 34th ICRC, The Hague, 6th August 2015

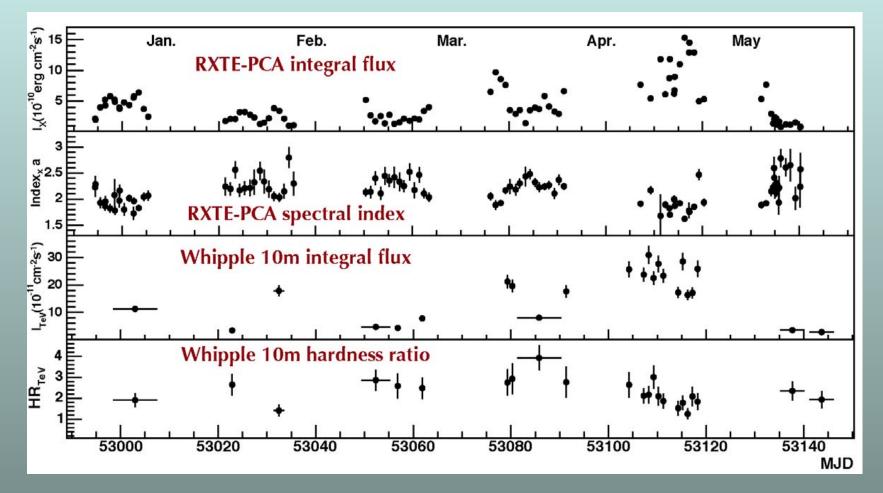

2) extragalactic sources

1997 discovery of strong variations of the flux of Mrk 421 + Mrk 501

Burst with ~30% intensity change within a day. Some changes on 15 min time scales. Time scale of variability constrains the size of the source: $\Delta x \approx c \cdot \Delta \tau$ ~size of solar system $\approx 1h$ **Objects are far away** $D = \frac{z \cdot c}{H_0} \approx \frac{0.033 \cdot 3 \cdot 10^5 \text{ km}}{65 \text{ km}} \approx 150 \text{ Mpc}$ estimate photon density at source: $n_{\gamma} \approx 10^{12} - 10^{15} \ \frac{1}{\mathrm{cm}^3}$ in the TeV range problem: at such energies the photon field is not transparent any more above 10 TeV $\gamma\gamma \rightarrow e^+e^$ threshold: $4E_{\gamma}\epsilon_{\gamma} > (2m_e c^2)^2 = 10^{12} \text{ eV}^2$

solution: relativistic beaming Source moves towards us at relativistic speeds.

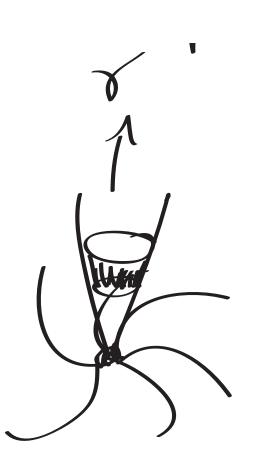

In moving coordinate system

- $R' = \gamma \cdot R$ i.e. $E' = \frac{1}{\gamma} \cdot E$ 1) the volume is a factor γ larger2) the energy is a factor $1/\gamma$ smaller
- --> the threshold is increased by a factor γ^2

since we observe photons at E > 10 TeV

 $\Rightarrow \gamma > 30$

i.e. relativistic jet is moving towards us

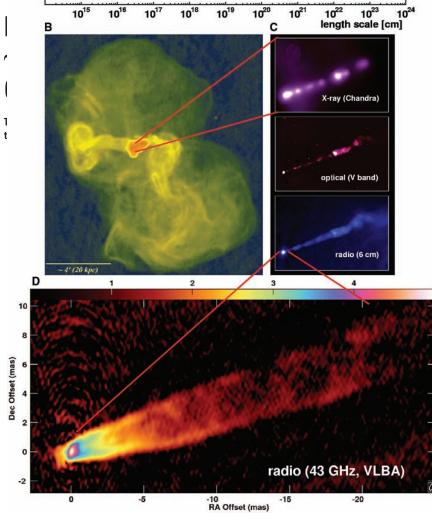

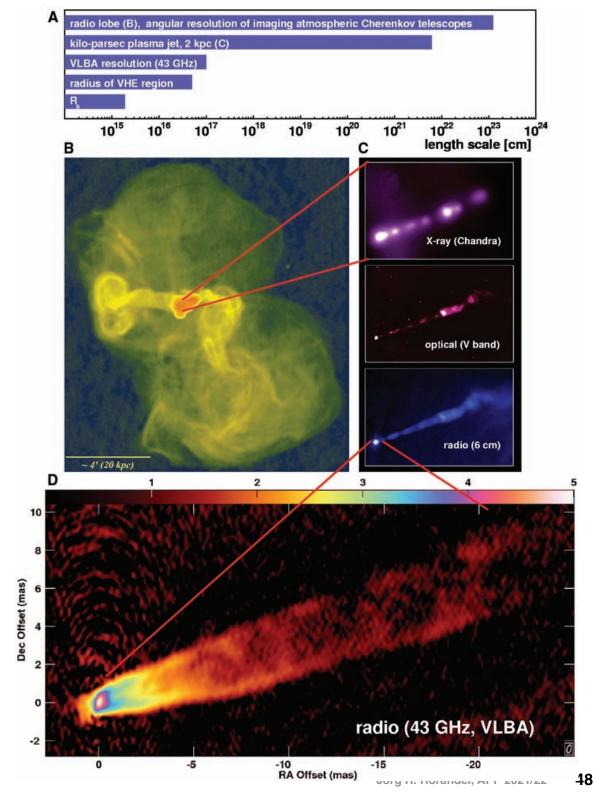

Fig. 1. M87 at different photon frequencies and length scales. (**A**) Comparison of the different length scales. (**B**) 90-cm radio emission measured with the VLA. The jet outflows terminate in a halo that has a diameter of ~80 kpc (15'). The radio emission in the central region is saturated in this image. [Credit: F. N. Owen, J. A. Eilek, and N. E. Kassim (32), NRAO/Associated Universities Incorporated/NSF] (**C**) Zoomed image of the plasma jet with an extension of 2 kpc (20''), seen in different frequency bands: x-rays (Chandra, top), optical (V band, middle), and radio (6 cm, bottom). Individual knots in the jet and the nucleus can be seen in all three frequency bands. The innermost knot HST-1 is located at a projected distance of 0.86 arc sec (60 pc, $\approx 10^5 R_s$) from the nucleus. [Credit: x-ray, NASA/Chandra X-Ray Observatory Science Center/Massachusetts Institute of Technology/H. Marshall *et al.*; radio, F. Zhou, F. Owen (NRAO), J. Biretta (Space Telescope Science Institute); optical, NASA/STSC//University of Maryland Baltimore County/E. Perlman *et al.* (*B*) (**D**) An averaged, and hence smoothed, radio image based on 23 images from the VLBA monitoring project at 43 GHz. The color scale gives the logarithm of the flux density in units of 0.01 millijansky per beam. The indication of a counter-jet can be seen, emerging from the core toward the lower left side. mas, milli–arc seconds.

Radio Imaging of the Very-High-Energy γ -Ray Emission Region in the Central Engine of a Radio Galaxy

The VERITAS Collaboration, the VLBA 43 GHz M87 Monitoring Team, the H.E.S.S. Collaboration, the MAGIC Collaboration*

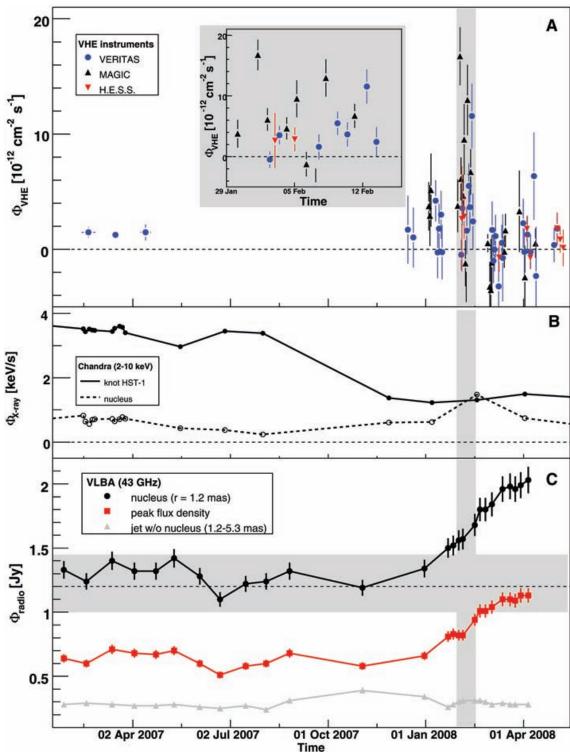

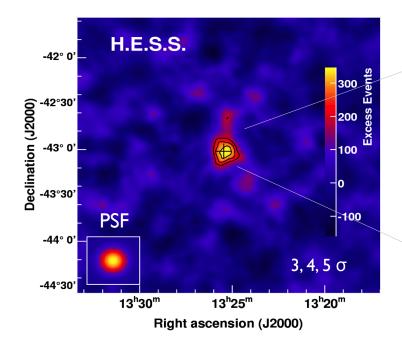

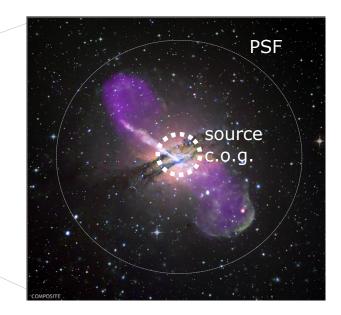

Fig. 2. Combined M87 light curves from 2007 to 2008. **(A)** VHE γ -ray fluxes (E > 0.35 TeV, nightly average), showing the H.E.S.S., MAGIC, and VERITAS data. The fluxes with statistical errors (1 SD) were calculated assuming a power-law spectral shape of $dN/dE \propto E^{-2.3}$. Monthly binned archival VERITAS data taken in 2007 are also shown (4). The systematic uncertainty in the flux calibration between the experiments was estimated to be on the order of 20%, based on Crab Nebula data. The regular gaps in the light curve correspond to phases of full moon during which no observations were possible. The inlay shows a zoomed version of the flaring activity in February 2008; the time span is indicated by the gray vertical box in all panels. **(B)** Chandra x-ray measurements (2 to 10 keV) of the nucleus and the knot HST-1 (28). **(C)** Flux densities from the 43-GHz VLBA observations are shown for (i) the nucleus (circular region with radius r = 1.2 milli—arc sec = 170R_s centered on the peak flux), (ii) the peak flux (VLBA resolution element), and (iii) the flux integrated along the jet between distances of r = 1.2 to 5.3 milli—arc sec (compare with Fig. 3). The error bars correspond to 5% of the flux. The shaded horizontal area indicates the range of fluxes from the nucleus before the 2008 flare. Whereas the flux of the outer regions of the jet does not change substantially, most of the flux increase results from the region around the nucleus.

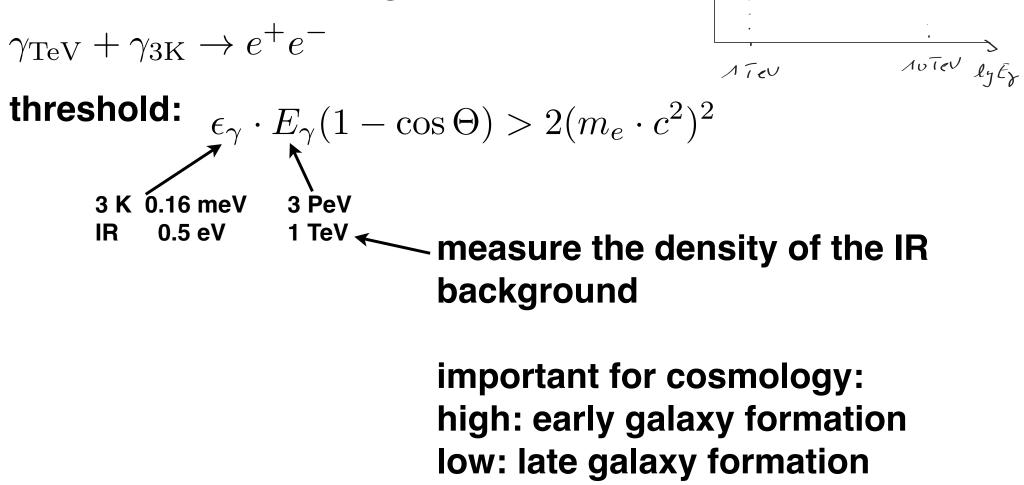

Centaurus A d~3.8 Mpc

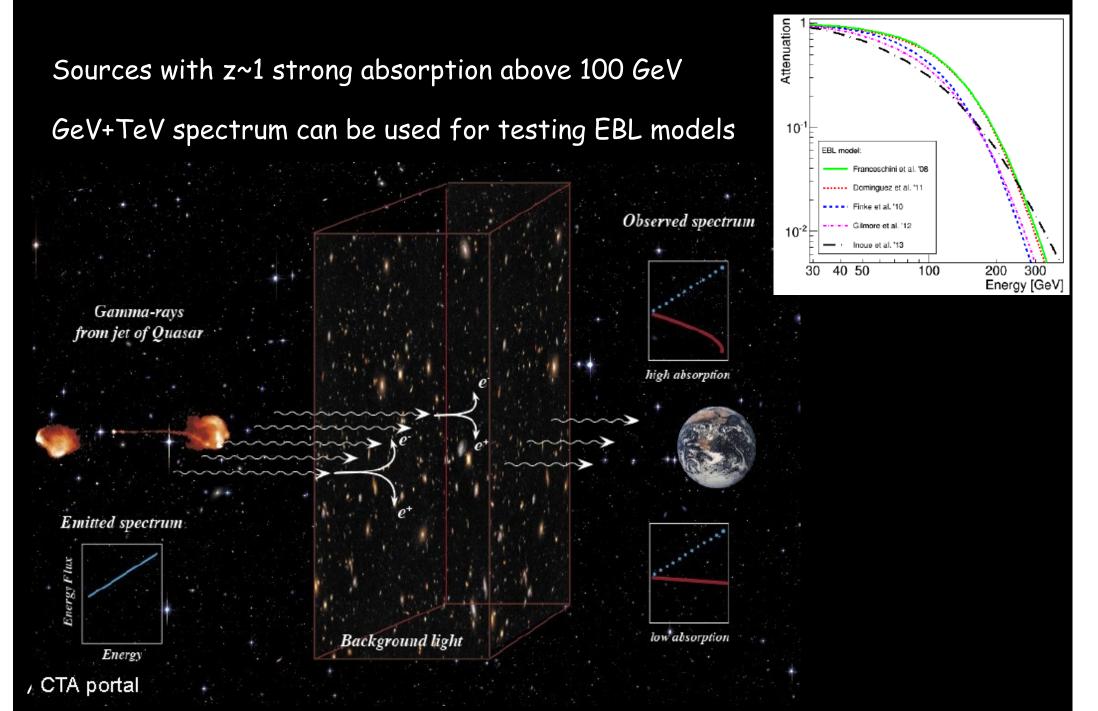

Energy spectrum of Mrk 421 & Mrk 501

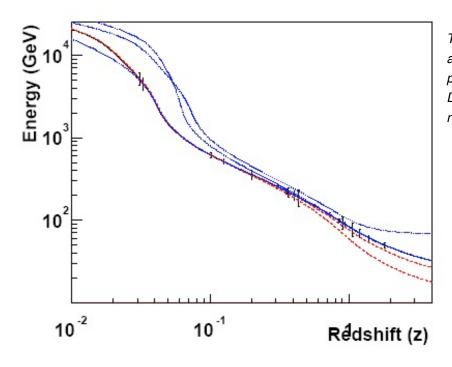

At high energies we expect absorption of gamma rays at photons of 3K microwave background

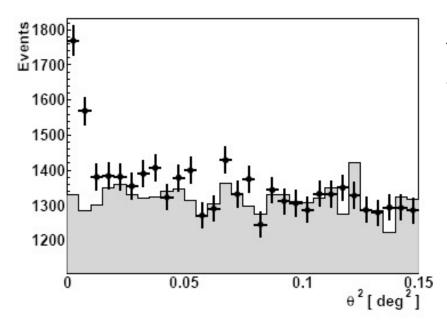

Absorption by the Extragalactic Background Light

The Blazar 1ES 1101-232 and the Gamma Ray Horizon

The "gamma ray horizon" defined as the distance (measured in redshift z) over which a gamma ray of a given energy will typically propragate before interacting with a photon of the extragalactic background light (from <u>Blanch and Martinez, 2005</u>). Different lines correspond to different models (and time scales) of galaxy formation, resulting in varying levels of background light.

Angular distribution of gamma-ray candidates detected by H.E.S.S. relative to the direction towards 1ES 1101-232. The gray area gives an estimate of the uniform background from cosmic-ray showers. The excess from the source has a significance of more than 11 standard deviations.

The Blazar 1ES 1101-232 and the Gamma Ray Horizon

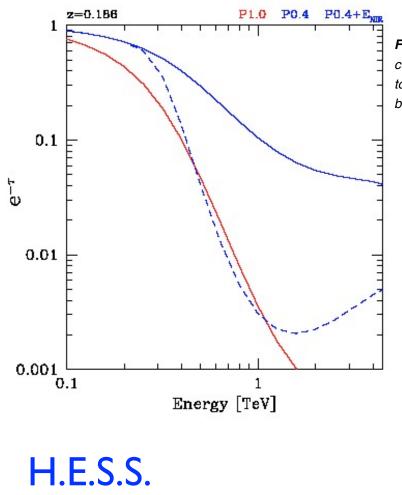

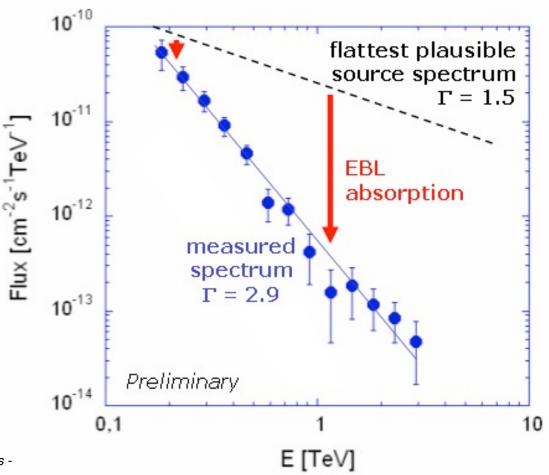

Fig. 3: Energy spectrum of gamma rays from 1ES 1101-232. The spectrum has a spectral index of 2.9. The dashed line indicates the flattest plausible spectrum generated by the AGN. Given that at low energies - around 0.1-0.2 TeV - the absorption of gamma rays has to be small - lacking appropriate UV target photons - absorption at 1 TeV has to be well below a factor 100, ruling out EBL models like the ones indicated by the red line or the dashed blue line in Fig. 2.

Fig. 2: Absorption of gamma rays from 1ES 1101-232 as a function of gamma-ray energy. The red curve shows the effect of typically assumed EBL levels, the blue curve the minimal EBL corresponding to the light of detected galaxies. The dashed curve indicates the effect of an additional near-infrared bump, as suggested by some direct EBL measurements.

Breaking the redshift barrier with PKS 1441+25 => Constraints on the EBL
